

## Guided Practice

### Lesson 1: Generating Product Specifications with MetaGPT

#### Overview:

In this guided practice, you will use MetaGPT's multi-agent ecosystem to generate a complete product specification for a new feature. You will provide a business prompt describing the product goal, then observe how MetaGPT allocates tasks across different roles (Product Manager, Designer, Engineer) to deliver a structured specification. The exercise focuses on logging into the platform, running a prompt-driven workflow, analyzing the agent collaboration, and reviewing the output. By completing this activity, you'll learn how to operate MetaGPT effectively, observe the role of multiple agents in structured product development, and evaluate how prompt engineering shapes AI-generated outputs.

#### Instructions:

- Use the MetaGPT platform to complete each step
- Work individually or collaborate in pairs to discuss design choices and approaches
- Spend approximately 30 minutes completing all steps of the demo
- Save or copy the generated output for later discussion

#### Scenario:

You are a product manager at a tech startup building a web-based habit tracking app. Your goal is to improve user retention by introducing a gamification feature. Using MetaGPT, generate a complete product specification that includes user stories, feature requirements, design considerations, and a development plan. Follow the guided steps below to complete the activity.

#### Steps to be followed:

1. Log in to MetaGPT
2. Write the prompt
3. Run the multi-agent workflow
4. Review the output

**Tools required:** MetaGPT platform

### **Discussion Questions (Optional):**

If time permits, discuss the following questions:

1. How does MetaGPT's multi-agent collaboration resemble a real product team's workflow?
2. Which part of the output (stories, requirements, design, or plan) would be most valuable for a PM before moving to development?

## Answer Key

### Step 1: Log in to MetaGPT

1.1. Go to <https://mgx.dev/> and sign in using your Google account

**Commented [KK1]:** Have they already signed up for this platform, or will they be doing it for the first time?

## Step 2: Write the prompt

2.1 Copy and paste the following prompt into MetaGPT's input box:

*You are a product manager at a tech startup building a web-based habit tracking app. The goal is to improve user retention by introducing a gamification feature. Generate a complete product spec including user stories, feature requirements, design considerations, and development plan.*

## Step 3: Run the multi-agent workflow

3.1 After pasting the prompt in the input box, click on the send icon

MetaGPT will deploy its multi-agent system.

**Commented [KK2]:** In this step we may add this note: it simulates a software development team with specialized AI agents (like a Product Manager and Engineer) to generate applications, analyze data, and automate research.

**Note:** Wait around five minutes for the system to generate the output

Expected output:

## Step 4: Review the output

4.1 Review the final deliverables that will include:

- User stories for gamification

- Feature requirements (badges, streaks, and rewards)

- Design considerations for UI/UX

- Development plan with milestones

By completing this guided practice, you understood how MetaGPT can take a single product idea and transform it into a structured specification and working prototype using its multi-agent system.

#### Discussion Questions with Answers:

**Q1. How does MetaGPT's multi-agent collaboration resemble a real product team's workflow?**

**Answer:** MetaGPT organizes work by assigning specific roles to agents, such as product manager, architect, engineer, and quality analyst. This mirrors how a real product team operates, where each member brings expertise to a particular function. The agents collaborate sequentially and iteratively, just like humans would: the PM defines requirements, the architect designs, the engineers produce code, and QA validates. The process highlights task delegation, specialization, and handoffs across functions — very similar to how cross-functional product teams coordinate in real-world organizations.

**Q2. Which part of the output (stories, requirements, design, or plan) would be most valuable for a PM before moving to development?**

**Answer:** For a product manager, the **requirements and user stories** are the most valuable outputs before moving to development. They establish clarity on what

needs to be built, why it matters, and how success will be measured. The requirements define scope and constraints, while user stories translate those requirements into user-centered tasks that developers can act upon. Design and planning artifacts are also useful, but without solid requirements and stories, downstream work risks misalignment. In practice, these outputs help a PM ensure that development begins with shared understanding and reduces the likelihood of rework later.
